(Received 1 July 1977)

Accepted without review at the request of Edwin L. Goldwasser under policy announced 26 April 1976

Dimuon production is studied in 400-GeV proton-nucleus collisions. A strong enhancement is observed at 9.5 GeV mass in a sample of 9000 dimuon events with a mass $m_{\mu^+\mu^-} > 5$ GeV.

We have observed a strong enhancement at 9.5 GeV in the mass spectrum of dimuons produced in 400-GeV proton-nucleus collisions. Our conclusions are based upon an analysis of 9000 dimuon events with a reconstructed mass $m_{\mu^+\mu^-}$ greater than 5 GeV corresponding to 1.6×10^{16} protons incident on Cu and Pt targets:

$$p + (\mathrm{Cu}, \mathrm{Pt}) \to \mu^+ + \mu^- + \text{anything}.$$

The produced muons are analyzed in a double-arm magnetic-spectrometer system with a mass resolution $\Delta m/m$ (rms) $\approx 2\%$.

The experimental configuration (Fig. 1) is a modification of an earlier dilepton experiment in the Fermilab Proton Center Laboratory.[1-3] Narrow targets (~ 0.7 mm) with lengths corresponding to 30% of an interaction length are employed.

Setup

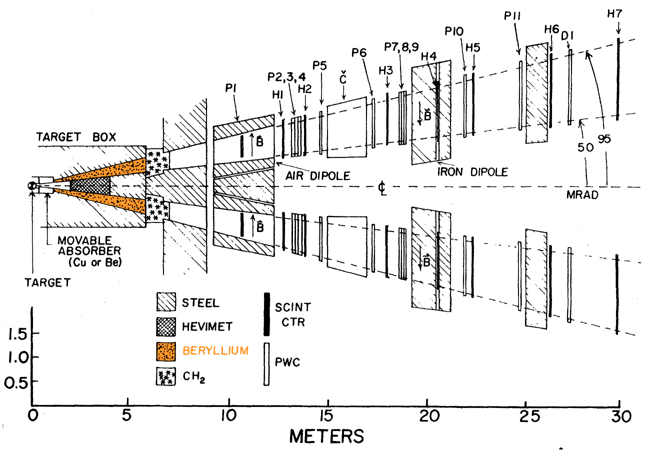
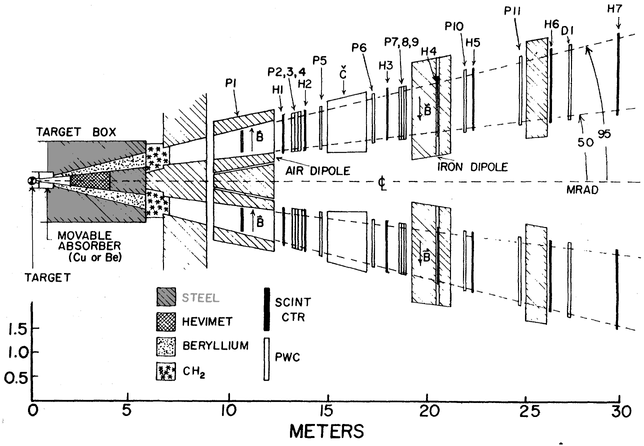
- 400 GeV proton beam shot on narrow target (Pt/Cu) with 30 % interaction length

Setup



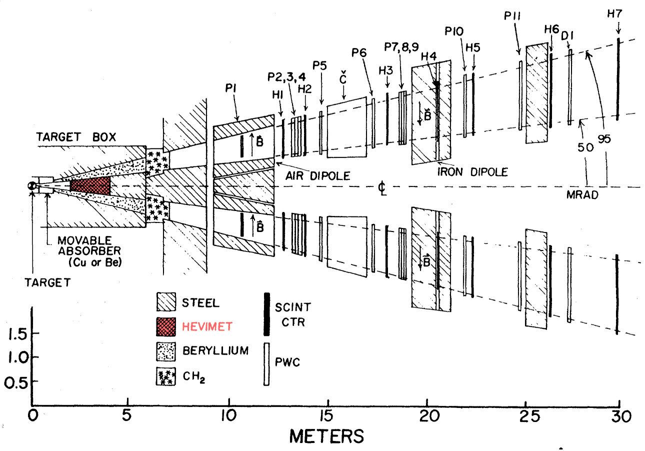
- hadron filter out of Be with 18 interaction length (3° to 5° horiz. and $\pm 0.5^\circ$ vert.)

Setup



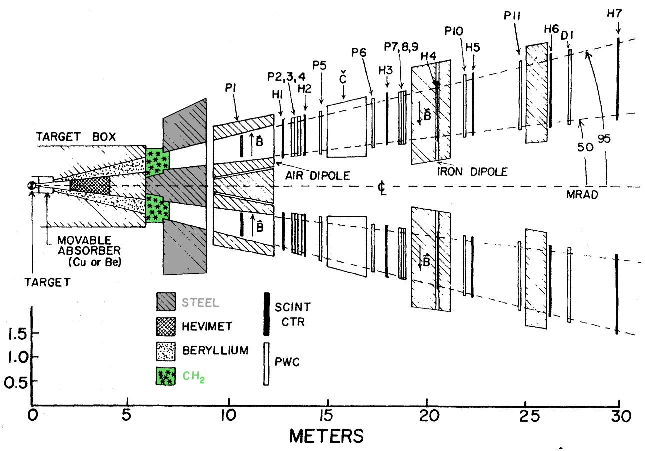
- heavy metal (Steel, W) shielding to minimise particle leakage

Setup



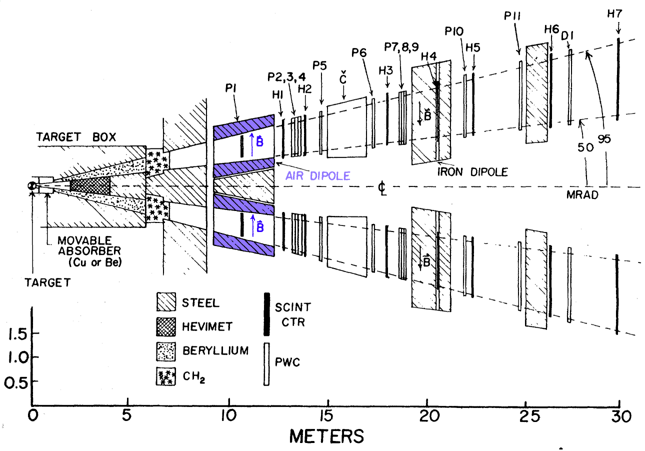
- tungsten beam dump

Setup



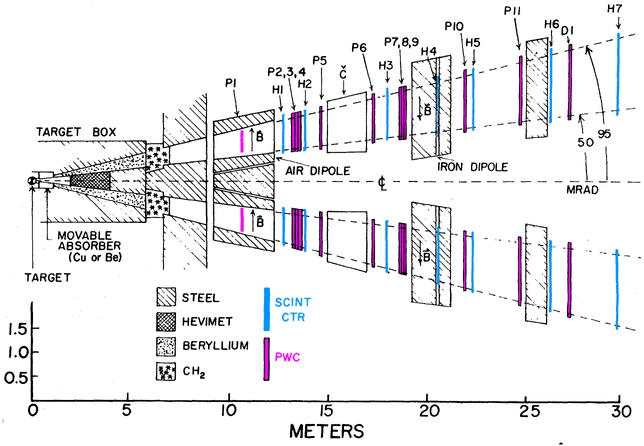
- additional shielding out of polyethylene and more steel

Setup



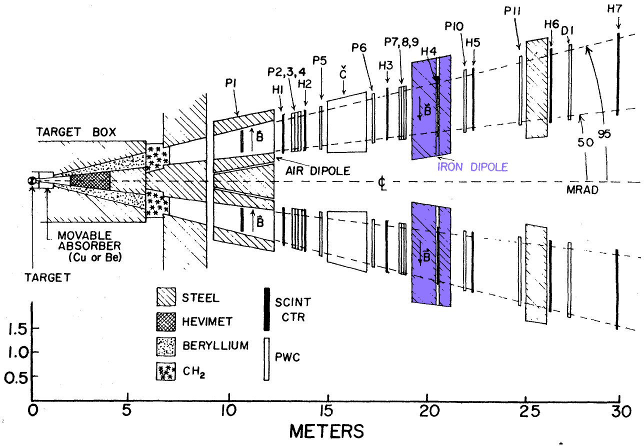
- spectrometer dipole magnets with horizontal field
- both arms are symmetric to drawing plane and detect μ^+ and μ^-

Setup



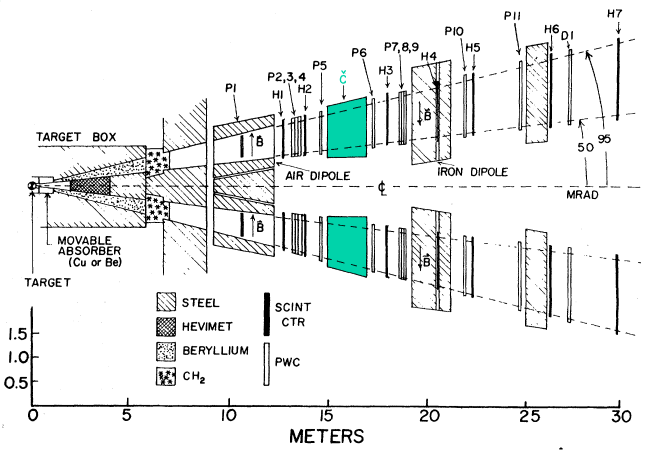
- scintillation hodometers and wire chambers for tracking (limit of 10×10^7 counts/s)

Setup



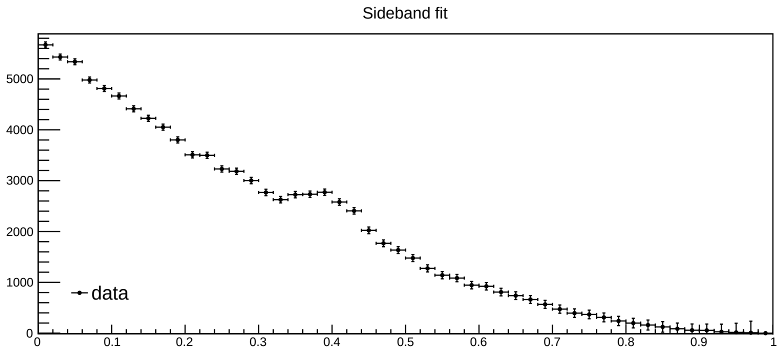
- solid iron magnet to partially refocus and redetermine muon momentum

Setup



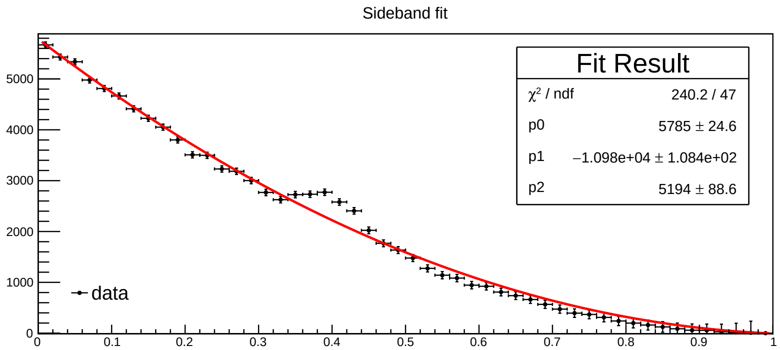
- Čerenkov counter to prevent low momentum muon triggers

Intermezzo: Sideband Fit



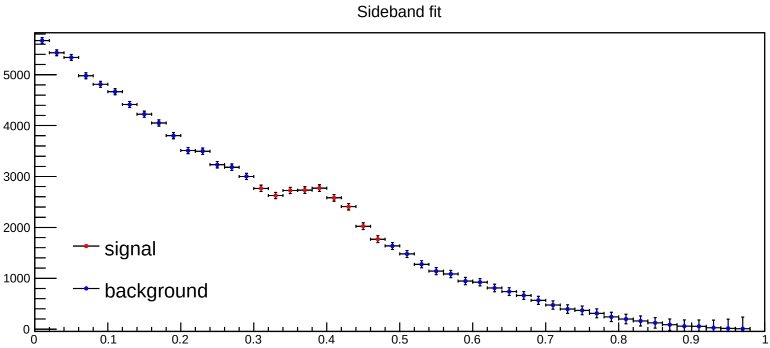
- typical shape of data in particle physics: continuous background with a small bump

Intermezzo: Sideband Fit



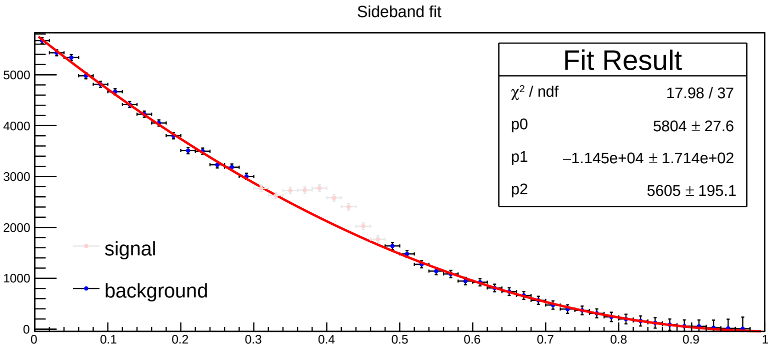
- background extraction with a fit of the whole set does not work well

Intermezzo: Sideband Fit



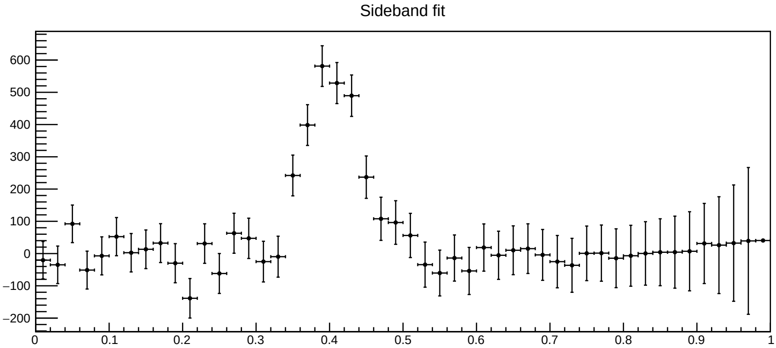
- divide the data set in a signal and two background parts ($\rightarrow$ side bands)

Intermezzo: Sideband Fit



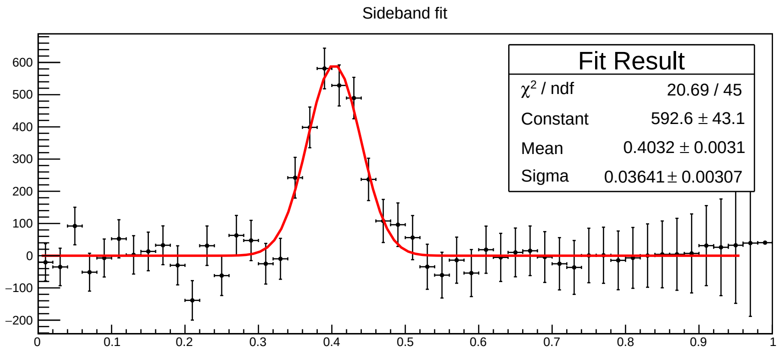
- fitting just the side bands yields a much better result

Intermezzo: Sideband Fit



- getting the signal distribution by subtracting the full data set by the fit

Intermezzo: Sideband Fit



- get width and position of the signal by a fit

Results

- statistically significant enhancement at 9.5 GeV $\mu^+\mu^-$ mass
- solid line background fit using side band method

$$\frac{d^2\sigma}{dmdy} = Ae^{-bm}$$

- fit expects 350 events in excluded region but 770 events in data
- bump wider than resolution of detector (FWHM: (0.5 ± 0.1) GeV)
- simple Gaussian fit of background subtracted data yields:

$$\mathbf{m = (9.54 \pm 0.04)\,GeV}$$
$$\mathbf{FWHM = (1.16 \pm 0.09)\,GeV}$$

- same goodness of fit with two Gaussians with fixed with of detector resolution → later Υ and Υ'

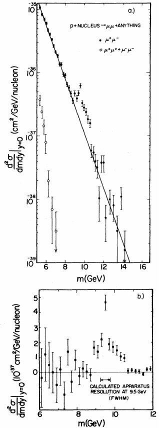


Figure: dimuon production cross section as a function of invariant mass

Verification

- same sign dimuon spectrum ($\mu^+\mu^+$ and $\mu^-\mu^-$)
  - upper limit on combined effects of accidental coincidences and hadronic decays
- re-measurement of the muon momentum by the second magnet and by PCW at the centre of the first magnet
  - avoid misidentified $\psi \longrightarrow \mu^+ + \mu^-$ at high mass
  - confirmed by clear separation of the ψ and ψ' in the Figure
- study of various subsets of the data with different magnetic fields
  - check for apparatus bias
- study of data with and without target
  - rule out signal created from beam dump

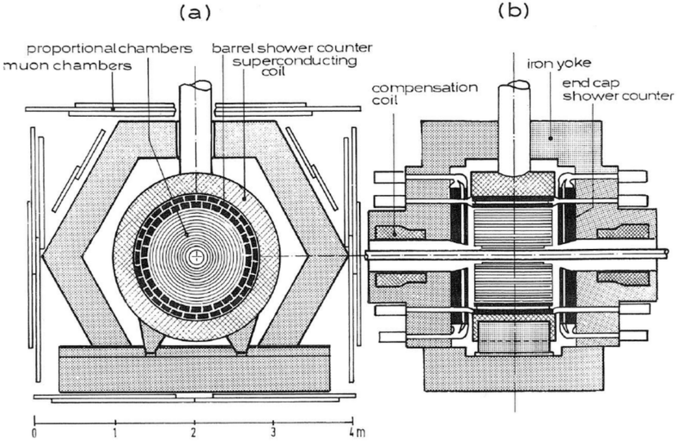
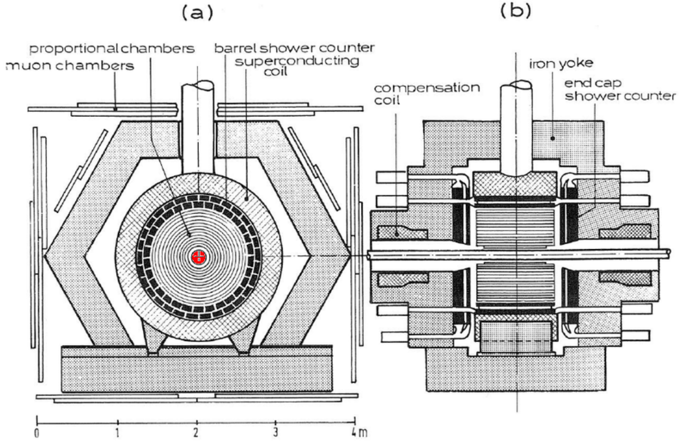
Received 9 May 1978

An experiment using the PLUTO detector has observed the formation of a narrow, high mass, resonance in e^+e^- annihilations at the DORIS storage ring. The mass is determined to be 9.46 ± 0.01 GeV which is consistent with that of the Upsilon. The gaussian width σ is observed as 8 ± 1 MeV and is equal to the DORIS energy resolution. This suggests that the resonance is a bound state of a new heavy quark-antiquark pair. An electronic width $\Gamma_{ee} = 1.3 \pm 0.4$ keV was obtained. In standard theoretical models, this favors a quark charge assignment of $-1/3$.

PLUTO Detector

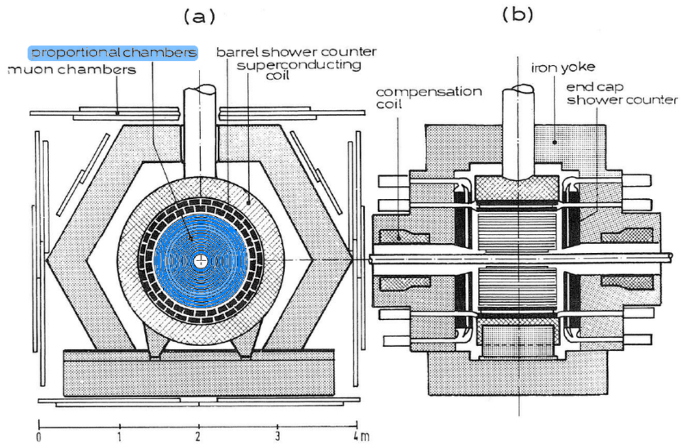


PLUTO Detector



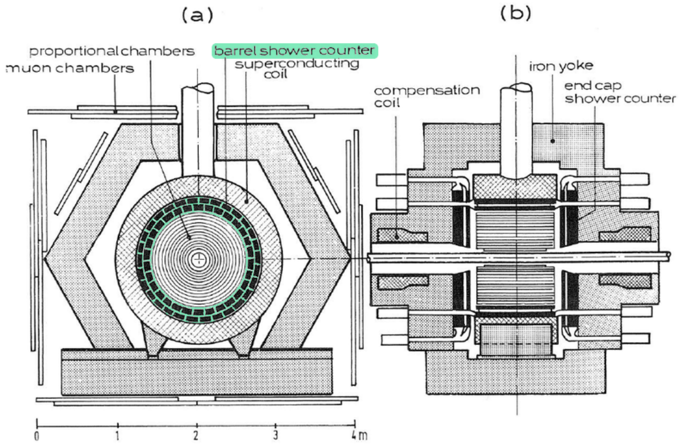
- up to 5 GeV electron beams collided in the centre

PLUTO Detector



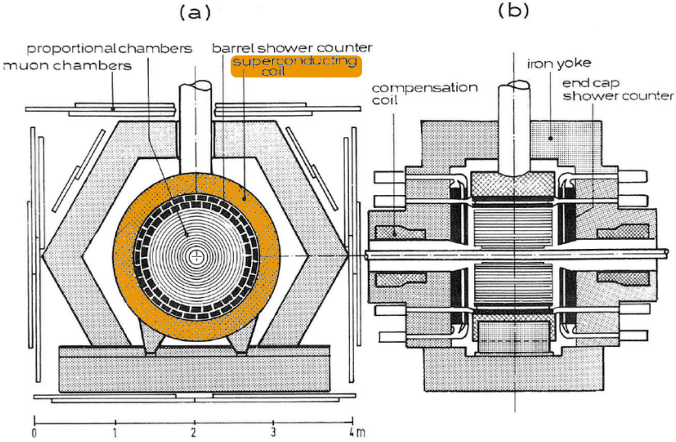
- cylindrical proportional wire chamber with 92 % coverage
- tracking and momentum measurement

PLUTO Detector



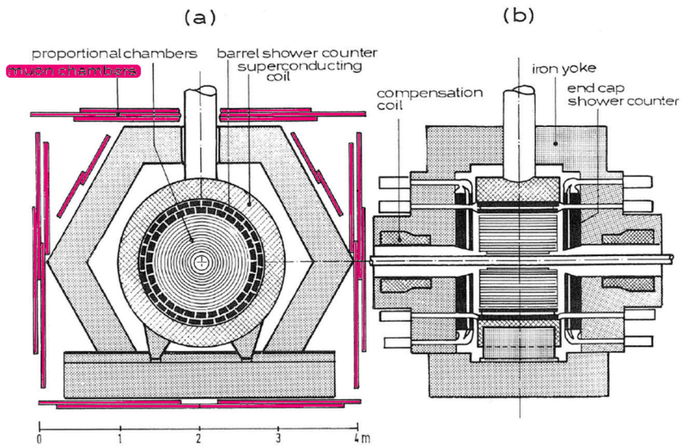
- cylindrical array of shower counters with 8.6 radiationlength and 94 % coverage
- calorimeter to measure the full energy

PLUTO Detector



- magnet with 1.69 T

PLUTO Detector



- muon chambers

Results

- acquiring cross section by scanning $\sqrt{s}$ in steps of either 5 GeV or 10 GeV
- only considering hadronic decay products
- remove $1/s$ background
- reduce cosmic ray background by use of bunch crossing time (bunched beam structure vs continuous background)

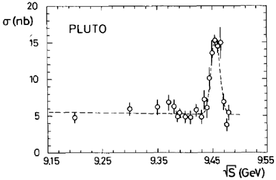


Figure: total cross section for hadron production

- remove QED events with coplanarity cut and shower recognition
- remove beam gas interaction by cuts on visible energy and missing mass
- fitting data with Gaussian yields:

$$\mathbf{m = (9.46 \pm 0.01)\,GeV}$$
$$\sigma_{\text{Gauss}} = \mathbf{(7.8 \pm 0.9)\,MeV}$$

Charge

- relation of total hadronic cross section to resonance mass and the resonance width

$$\int \sigma_h dM = \frac{6\pi^2}{{M_R}^2} \frac{\Gamma_{ee}\Gamma_h}{\Gamma_{tot}}$$

- standard assumption: $\Gamma_{tot} \approx \Gamma_h \rightarrow$ direct measurement of Γ_{ee}

$$\Gamma_{ee} = (1.3 \pm 0.4)\,\mathrm{keV}$$

- theoretical predictions from the same model:

Decay Mode	Width [keV]	
	$e = \pm 1/3$	$e = \pm 2/3$
$\mu^+\mu^-$	0.70 ± 0.09	2.8 ± 0.4

- **implies charge of -⅓ for the bottom quark**

Section 3

The Truth Quark

Introduction

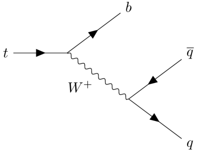
- in early 90s all SM particles except H and t-quark discovered
- beauty discovery $\rightarrow$ weak isospin partner was undoubted
- quark masses are fundamental parameters in the SM
- early estimates: $\mathrm{m_t} \approx 3\mathrm{m_b} \approx 15\,\mathrm{GeV}$
- many new accelerator could only push limits higher:
- TRISTAN (e^+e^-) at KEK (Tsukuba, Japan) with $\sqrt{s} = 61.4\,\mathrm{GeV} \rightarrow 30.2\,\mathrm{GeV}$
- Sp$\bar{\mathrm{p}}$S at CERN with $\sqrt{s} = 630\,\mathrm{GeV} \rightarrow 69\,\mathrm{GeV}$
- SLC (e^+e^-) at Stanford and LEP (e^+e^-) at CERN $\rightarrow$ $^1/_2\mathrm{m_t}$
- hadron collider needed ($\rightarrow$ Tevatron)

Decay Channels (1)

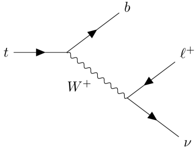
- estimate on m_t in 1994: $\sim$180 GeV
- prior to discovery: behaviour completely predicted by SM
- $m_t > m_W \rightarrow$ main decay channel ($\sim$96 %): **$t \longrightarrow W^+ b$**

$$\Gamma_t = \frac{G_F m_t^3}{8\pi\sqrt{2}} \left(1 - \frac{m_W^2}{m_t^2}\right)^2 \left(1 + 2\frac{m_W^2}{m_t^2}\right)$$

- width for the expected mass: $\sim$1 GeV $\rightarrow$ decay before hadronisation



(a) $\sim$67 %

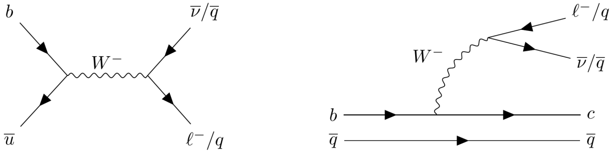


(b) $\sim$33 %

- leptonic decay equally splits up into e, μ and τ

Decay Channels (2)

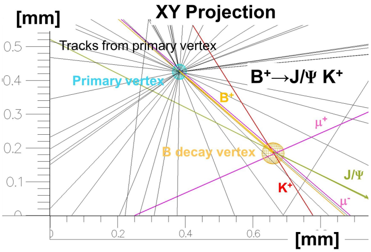
- top mostly pair produced via $q\bar{q} \longrightarrow t\bar{t}$ or gluon fusion: $gg \longrightarrow t\bar{t}$
- main decay of the top pair: $t\bar{t} \longrightarrow W^+bW^-\bar{b}$
- b decay:



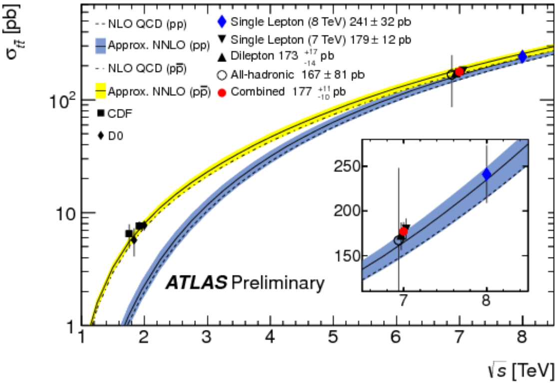
- typical signals:
  - 2 b-jets + dilepton (e^+e^-, $\mu^+\mu^-$, $e^+\mu^-$, μ^+e^-)
  - 2 b-jets + single lepton + two jets
  - 2 b-jets + 4 jets
- huge background on pure QCD process due to other more common QCD processes
- how to discriminate b-jets from other jets?

B-Tagging

- most jets from light partons (u,d,s) or gluons
- lower rates from c, and b quarks
- interesting physics from b $\rightarrow$ top, higgs, supersymmetry or new phenomena
- b longer lifetime than other partons
- look for secondary vertices (away from primary vertex $\rightarrow$ interaction point)
- first reconstruct primary vertex:
  - cluster all tracks together and determine likelihood they origin from common vertex
  - vertex with highest p_T = primary vertex
- background for secondary vertices (mostly from light flavoured jets)
  - K-short Meson
  - lambda Baryon
  - photon conversion



$t\bar{t}$ Cross Section



- cross section extracted from SM
- Tevatron Lumi in 1995: $10 \times 10^{30}\,\mathrm{cm}^{-2}\,\mathrm{s}^{-1}$

$$R_{t\bar{t}} = \sigma_{t\bar{t}}\mathscr{L} = 0.1\,\mathrm{Hz}$$

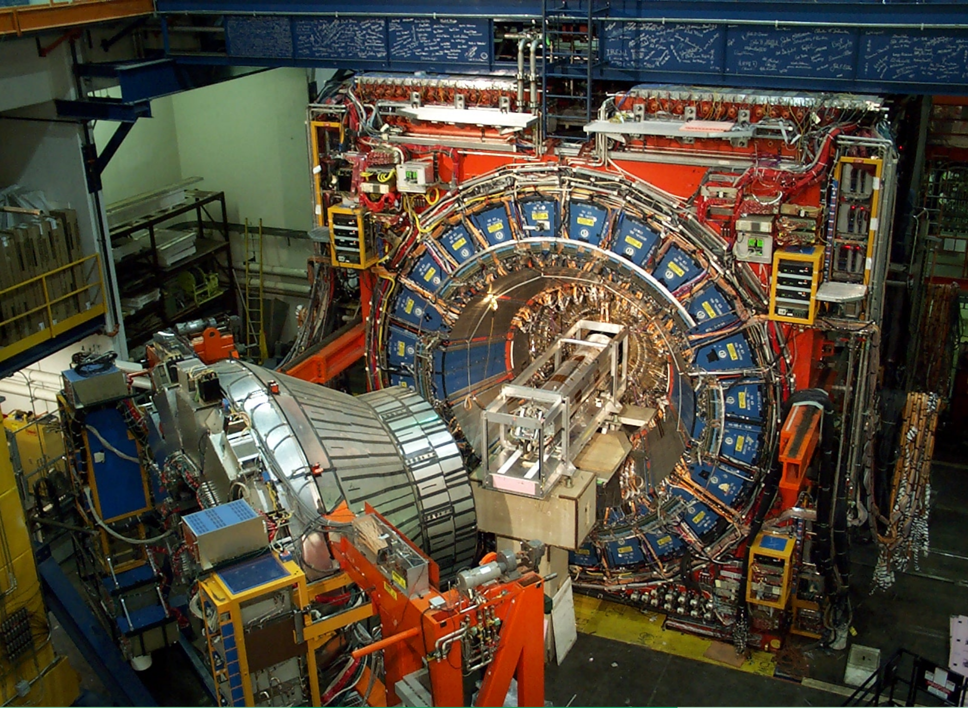
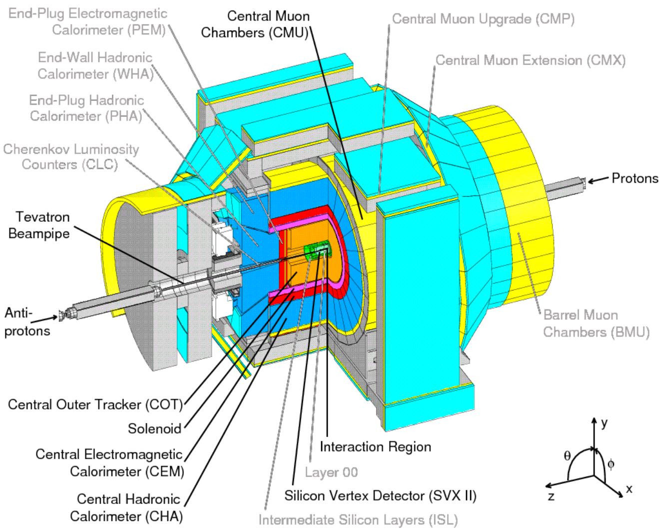
We establish the existence of the top quark using a 67 pb^{-1} data sample of $\bar{p}p$ collisions at $\sqrt{s} = 1.8$ TeV collected with the Collider Detector at Fermilab (CDF). Employing techniques similar to those we previously published, we observe a signal consistent with $t\bar{t}$ decay to $WWb\bar{b}$, but inconsistent with the background prediction by 4.8σ. Additional evidence for the top quark is provided by a peak in the reconstructed mass distribution. We measure the top quark mass to be $176 \pm 8(\mathrm{stat}) \pm 10(\mathrm{syst})$ GeV/c^2, and the $t\bar{t}$ production cross section to be $6.8^{+3.6}_{-2.4}$ pb.



CDF Detector



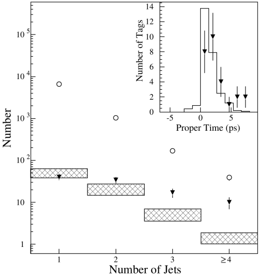
Introduction

- paper from 1994 with estimate on mass and cross section
- using dataset of $19\,\mathrm{pb}^{-1} + 47\,\mathrm{pb}^{-1}$ ($\rightarrow \sim 400$ events)
- looking at two decay channels
  - dilepton
  - lepton + jets
- both data samples subsets of events with isolated leptons with high $P_T > 20\,\mathrm{GeV}$
- cut on invariant mass of dilepton $75\,\mathrm{GeV} < m_l < 105\,\mathrm{GeV} \rightarrow$ exclude Z events
- main background reduction by b-tagging
  - reconstruction of secondary vertices from b decay in SVX $\rightarrow$ SVX tag
  - finding additional leptons from b decay in ECAL $\rightarrow$ SLT tag

Lepton + Jets Channel

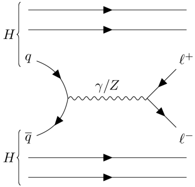
SVX tagging:

- search for secondary vertices with three ore more tracks
- then search for two ore more tracks with more stringed track and vertex quality
- efficiency estimated by e, μ samples with enriched b decays (96 % agreement to MC)
- tagging efficiency: $(42 \pm 5)\,\%$
- backgrounds:
  - recoil of heavy quark pairs against W
  - mistags
- for W+ ≥ 3 jets: observation of 27 tags with bg of (6.7 ± 2.1) tags
- decay lifetime of SVX tags agrees well with MC



Dilepton Channel

- major backgrounds:
  - Drall-Yan process
  - $Z \longrightarrow \tau\tau$
  - misidentified hadrons
  - WW, $b\bar{b}$



- first three bg calculated by data and last two by MC
- cuts:
  - $\not{E}_T \geq 10\,\text{GeV}$
  - number of jets ≥ 2
- reduces Drell-Yan bg (very little $\not{E}_T$)
- correct for jet energy mismeasurement

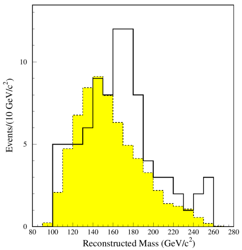
Results

Channel	**SVX**	**SLT**	**Dilepton**
Observed	27 tags	23 tags	6 events
Expected background	6.7 ± 2.1	15.4 ± 2.0	1.3 ± 0.3
Background probability	2×10^{-5}	6×10^{-2}	3×10^{-3}

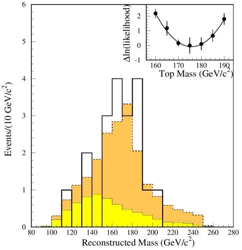
- combined likelihood of the background fluctuating up: 1×10^{-6} ($4.8\,\sigma$)

Mass Reconstruction

- kinematically mass reconstruction by use of single lepton + 4 jet events
- $t\bar{t} \longrightarrow WbW\bar{b} \longrightarrow q\bar{q}b\ell\nu\bar{b}$
- predicted mix of 30 % $t\bar{t}$ and 70 % W + jets bg (yellow)
- reducing bg by applying SVX and SLT tags
- get best top mass by using MC with W + jets bg and varying the top mass



(a) before b-tagging



(b) after b-tagging

Combined Results

- combined signal size and mass distribution
- probability for and upward fluctuation of the bg:

$$\mathbf{P_c = 3.7 \times 10^{-7}\ (5.0\,\sigma)}$$

- reconstructed mass:

$$\mathbf{m_{top} = 176 \pm 8 \pm 10\,GeV/c^2}$$

- cross section:

$$\sigma_{\mathbf{t\bar{t}}} = \mathbf{6.8^{+3.6}_{-2.4}\,pb}$$
